Stress Fields and Strut-and-Tie Models as a Basic Tool for Design and Verification in Second Generation of Eurocode 2

Campos de tensiones y modelos de bielas y tirantes: herramientas fundamentales para el proyecto y comprobación de estructuras de hormigón en la segunda generación del Eurocódigo 2

ABSTRACT

Within the frame of the revision of the Eurocode 2 for concrete structures, the section devoted to strut-and-tie design has been updated to enhance its applicability, its consistency with other sections and its ease-of-use. As a result, a number of changes have been introduced. Namely, the use of stress fields and their combination with classical strut-and-tie models has been incorporated. The changes in this section can be seen as an effort to provide a more comprehensive and general tool for designers, that can be transparently applied to any structural member with sufficient reinforcement for crack control. In this paper, the consistency between the strut-and-tie and the stress field methods is clarified as well as the fundamentals of the revision performed in Eurocode 2. The paper also elaborates how the code can be used for advanced analyses, considering in an explicit manner the compatibility of deformations to obtain refined estimates of the structural resistance.

KEYWORDS: Strut-and-tie, stress fields, limit analysis, shear, discontinuity regions, shell design.

RESUMEN

En el marco de la revisión del Eurocódigo 2 para estructuras de hormigón, se ha actualizado el capítulo dedicado al diseño mediante modelos de bielas y tirantes, mejorando su coherencia con otras secciones así como su facilidad de uso. Para ello, se han introducido una serie de cambios, como la consideración del método de campos de tensiones y su combinación con los modelos clásicos de bielas y tirantes. Estos cambios pueden considerarse como un esfuerzo para proporcionar una herramienta más completa y general. En este artículo, se clarifica la coherencia entre los métodos de bielas y tirantes y los campos de tensiones, así como los principios de la revisión efectuada para el Eurocódigo 2. También se explica cómo puede utilizarse dicha norma para realizar análisis avanzados, considerando de manera explícita la compatibilidad de deformaciones con el objetivo de obtener estimaciones precisas de la resistencia.

PALABRAS CLAVE: Bielas y tirantes, campos de tensiones, análisis límite, cortante, regiones de discontinuidad, diseño de lajas.

1.

INTRODUCTION

Reinforced concrete as a structural material was introduced at the end of the 19th century through a number of patents [1-3].

Almost from the beginning, the engineers realised that traditional design methods rooted in linear elastic theory could not adequately be used to explore the full potential of the new composite material. A new approach was therefore needed and within

respect (at nodes A and C) the minimum angle $\theta_{cr} = 20^\circ$ recommended by the PrEN1992-1-1:2022.

Grounded on these observations, some refinements can be introduced in the strut-and-tie model, Figure 9e, by providing spreading of the struts. Such spreading allows fulfilling the requirements in terms of minimum angles between struts and ties, and needs the arrangement of additional reinforcement in the form of horizontal and vertical bars (stirrups or pins, see Figure 9f). With respect to the region at the right of the bent of the bar, the fan region (with a steeper angle of the resulting strut) and the constant-angle compression field region (with a flatter angle of the resulting strut) can be designed following the standard procedure for shear in members with transverse reinforcement.

Finally, detailed checks can be performed on the basis of stress fields at the critical regions (nodal regions A and B), ensuring that sufficient space is available for development of the struts and nodal regions. To that aim, a constant and safe value of the efficiency factor is adopted ($\nu = 0.55$ ac-

counting for the angles of the struts and ties), allowing to analyse all nodes under plane-stress hydrostatic conditions, see Figure 9f. The results show that this aspect is not critical. Also, detailing of the reinforcement can be consistently established, in terms of type of reinforcement and anchorage lengths.

For a final optimisation, or in case the performance of the detailed needed to be assessed, a refined EPFS analysis could also be performed. The results are shown in Figure 10 for two cases. The first considers only inclined reinforcement and stirrups at the right of the bend (Figure 10a-d), corresponding to the reinforcement layout of Figure 9d. The latter considers also an additional horizontal and vertical reinforcement in the discontinuity region (Figures 10e-h), corresponding to the reinforcement layout of Figure 9f. In all cases, the load was applied by means of a stiff plate, distributing it into the concrete surface.

When only inclined reinforcement is provided in the discontinuity region (Figures 10a-d), a similar response to that of Figure 9d results, with an inclined compression field devel-

Figure 9. Example of application: (a) element investigated; (b) critical detail; (c) analysis based on thrust line; (d) strut-and-tie model (with lines for analysis with graphic statics shown in light grey); (e) refined strut-and-tie model; (f) stress field verifications and reinforcement layout; and (g) enhanced detailing.

EN 1992-1-1:2004 (E)

(5) Where proprietary products are used as shear reinforcement, $V_{Rd,cs}$ should be determined by testing in accordance with the relevant European Technical Approval. See also 9.4.3.

6.5 Design with strut and tie models

6.5.1 General

(1)P Where a non-linear strain distribution exists (e.g. supports, near concentrated loads or plain stress) strut-and-tie models may be used (see also 5.6.4).

6.5.2 Struts

(1) The design strength for a concrete strut in a region with transverse compressive stress or no transverse stress may be calculated from Expression (6.55) (see Figure 6.23).

Figure 6.23: Design strength of concrete struts without transverse tension

$$\sigma_{Rd,max} = f_{cd} \quad (6.55)$$

It may be appropriate to assume a higher design strength in regions where multi-axial compression exists.

(2) The design strength for concrete struts should be reduced in cracked compression zones and, unless a more rigorous approach is used, may be calculated from Expression (6.56) (see Figure 6.24).

Figure 6.24: Design strength of concrete struts with transverse tension

$$\sigma_{Rd,max} = 0,6 v f_{cd} \quad (6.56)$$

Note: The value of v for use in a Country may be found in its National Annex. The recommended value is given by equation (6.57N).

$$v = 1 - f_{ck}/250 \quad (6.57N)$$

(3) For struts between directly loaded areas, such as corbels or short deep beams, alternative calculation methods are given in 6.2.2 and 6.2.3.

6.5.3 Ties

(1) The design strength of transverse ties and reinforcement should be limited in accordance with 3.2 and 3.3.

(2) Reinforcement should be adequately anchored in the nodes.

3. Compression fields and struts

Action:

$$\sigma_{cd} = \frac{|F_{cd}|}{b_c \cdot t}$$

3. Compression fields and struts

Action:

$$\sigma_{cd} = \frac{|F_{cd}|}{b_c \cdot t}$$

Resistance:

$$\sigma_{cd} \leq \nu \cdot f_{cd}$$

Plastic strength

(Muttoni, 1990)

$$f_{cd} = \eta_{cc} \cdot k_{tc} \frac{f_{ck}}{\gamma_C}$$

$$\eta_{cc} = \left(\frac{f_{ck,ref}}{f_{ck}} \right)^{\frac{1}{3}} \leq 1,0$$

Compression softening

(Robinson and Démorieux, 1962)

(Vecchio and Collins, 1986)

3. Compression fields and struts

Action:

$$\sigma_{cd} = \frac{|F_{cd}|}{b_c \cdot t}$$

Resistance:

$$\sigma_{cd} \leq v \cdot f_{cd}$$

$$v = \frac{1}{1,0 + 110\varepsilon_1} \leq 1,0$$

3. Compression fields and struts

Action:

$$\sigma_{cd} = \frac{|F_{cd}|}{b_c \cdot t}$$

Resistance:

$$\sigma_{cd} \leq v \cdot f_{cd}$$

$$v = \frac{1}{1,0 + 110\varepsilon_1} \leq 1,0$$

$$\varepsilon_x \approx \varepsilon_{yield} / 2 \approx 0.001$$

$$v = \frac{1}{1,11 + 0,22 \cdot \cot^2 \theta_{CS}}$$

$$\varepsilon_1 = \varepsilon_x + (\varepsilon_x + 0.001) \cdot \cot^2 \theta$$

(but ε_x might have other values for panels with for instance uniform strain level)

3. Compression fields and struts

Action:

$$\sigma_{cd} = \frac{|F_{cd}|}{b_c \cdot t}$$

Resistance:

$$\sigma_{cd} \leq v \cdot f_{cd}$$

$$v = \frac{1}{1,0 + 110\varepsilon_1} \leq 1,0$$

Eq. (8.119) (Eq. (8.121) considering $\varepsilon_1 = \varepsilon_x + (\varepsilon_x + 0.001) \cot^2 \theta$, with $\varepsilon_x = 0.001$)
Constant values §8.5.2(4)

$$v = \frac{1}{1,11 + 0,22 \cdot \cot^2 \theta_{cs}}$$

4. Nodal regions

CCC

No need for detailed checks, v
is governed by strut conditions

4. Nodal regions

CCC

CCT

4. Nodal regions

CTT

a) strut-and-tie model and equilibrium of forces

b) strut-and-tie model and stress field for the deviation force of a bent bar

c) strut-and-tie model and stress field for anchorages outside the node

d) strut-and-tie model and stress field for anchorages inside the node with deviations occurring due to bond

4. Nodal regions

CTT

a) strut-and-tie model and equilibrium of forces

b) strut-and-tie model and stress field for the deviation force of a bent bar

c) strut-and-tie model and stress field for anchorages outside the node

d) strut-and-tie model and stress field for anchorages inside the node with deviations occurring due to bond

TTT

TTT nodes, where only ties reach the node. TTT nodes may be used only if consistent values of the strength reduction factor ν in the node are adopted accounting for anchorage, detailing and strains according to 8.5.2(5).

5. Example of application

- Existing school at Lausanne (Switzerland)
- Refurbishment works, including a new courtyard
- Engineer: Antonio Garcia (Muttoni et Fernández, ingénieurs conseils SA)

5. Example of application

5. Example of application

- Span length $L = 12.1$ m
- Main girders $b = 50$ cm
- Unusual shape of the support
- Heavily reinforced in bending
- How to approach a suitable detailing for the support region?
